

BIOLOGY

1) ATP and NADPH

2) Mitochondria

3) RBC

4) Transpiration and guttation

5) Glomerulus and Bowman's capsule

6) Age of plants

7) In plants, the respiratory gases simply diffuse in and outside of the cells by cell division. In ~~plants~~ animals there is gaseous transport of gases. Plants don't stop breathing instead they respire through their leaves. Animals show breathing.

8) The light reaction is the first stage of photosynthesis which traps light energy to produce ATP and NADPH whereas dark reaction is the second step in which these energy are used to produce glucose.

9) a) proteolytic enzyme,

b) When there is a absence of oxygen it produces lactic acid which causes cramps.

11) a) Alveoli are covered with blood capillaries so that the exchange of gases takes place between the membrane of alveoli and the surrounding capillaries.

b) The cartilaginous ring is strong and flexible. It supports the trachea and prevents it from collapsing.

tiny gas sacs
of the cells
which animals
out of gases
through instead

g and
less

10) Because the temperature is very low
and no evaporation takes place and
no sweating occurs. Because of this
we ~~are~~ release more urine

11) 1) renal gland and malpighian tubules

2) skin, lungs and liver

12) 4 - left atrium
5 - right atrium

11) 3 - superior vena cava
6 - inferior vena cava

It carries the important function of
carrying oxygen poor blood to the heart's
right atrium

11) veins

14) The blood passes through the heart
twice. Once through the right half
in the form of deoxygenated blood to lungs
and next through the left part of
the lungs to all parts of the body

10a) To digest the food the enter our
stomach
