Chemistry.

1. Buckminster fullerene is allotrope of carbon with 60 carbon atoms.

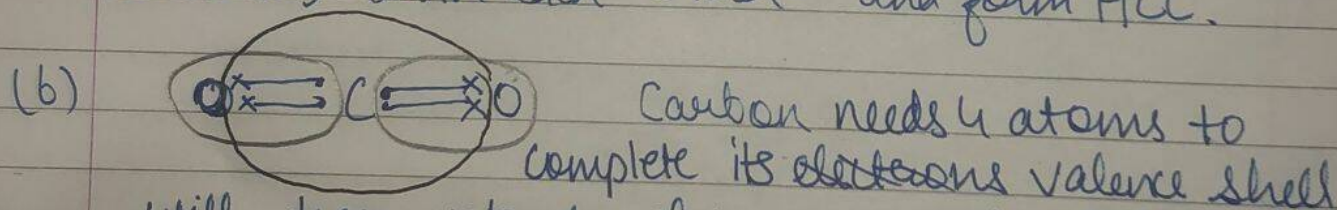

Covalent bonds are formed by sharing of electrons by atoms of non metals.

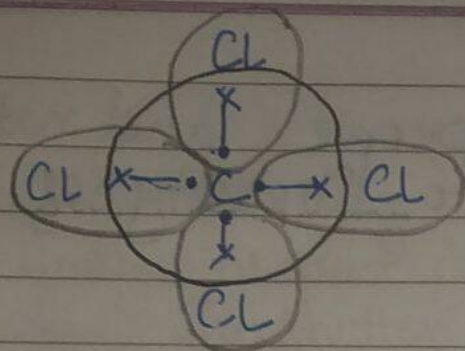

- (i) Bond ~~between non metals~~ formed by non metals.
- (ii) weak force of attraction between bonds.

hydrogen and chlorine need 1 ~~atom~~ ^{electron} to complete their valence shell so they share their electrons with each other and form HCl.

will two molecules of oxygen need 2 electrons each for completing their ~~shell~~ valence shell so carbon forms two double bonds with oxygen molecules and form CO_2

The 4 atoms of chlorine share their electrons with carbon so that each atom complete its valence shell. This results in formation of CCl_4 .
