

Biology

1. ATP and NADPH_2
2. Mitochondria
3. RBC
4. Transpiration
5. Glomerulus and Bowman's capsule
6. None of these

7. respiration in plants occur through the pores on the leaves known as stomata
In animals there are special organs such as lungs which help in respiration

Light reaction

Dark reaction

i) it occurs in presence of sunlight

it does not require sunlight to occur

ii) absorbs light and oxygen

it only absorbs CO_2

iii) end products are ATP, oxygen

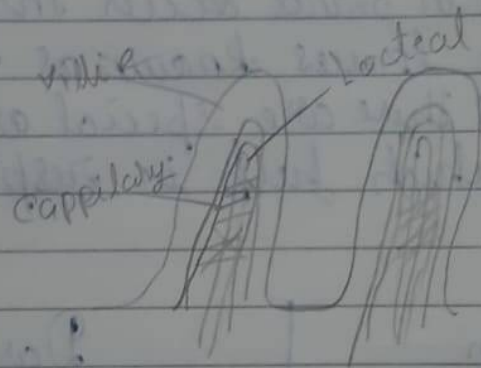

It end products are glucose

10. a role of acid in stomach are

11

- i) it kills bacteria in food
- ii) It creates an acidic which allows pepsin to start digesting proteins

b. Lacteal is a special tissue which is surrounded with blood capillaries which allows the absorption of food and increases the surface area

9. a The enzymes that act on protein are trypsin and pepsin.

b. in animals the pyruvate turns into lactic acid in ~~animal~~ muscle cells of animals

11. a The Alveoli are covered in blood vessels so that the exchange of gases can occur. due to this alveoli is called the functional unit of lungs

b. The wall of trachea has cartilaginous rings so that the trachea does not collapse in low air pressure

12a Since humans don't sweat during the winter the waste product has to be removed by the urine

b. The accessory excretory organs are:

i) Kidneys

ii) bladder

iii) Urethra

13. i) Mitral and tricuspid valve

ii) Vena Cava

iii) Arteries

iv) Since humans are warm blooded creatures double circulation is necessary in order to maintain circulation
