

Biology

- (1) (4) Both (1) & (2)
(2) ~~Mitochondria~~ (3) Cytoplasm and mitochondria
(3) (1) RBC
(4) ~~Transpiration~~ (2) Transpiration
(5) (4) 1 & 2
(6) (4) None of these

(7) Respiration in Plants

- Plants don't breathe, they respire
- CO_2 is released during respiration which is used during photosynthesis
- Plants photosynthesize their glucose.

Respiration in Animals

- Animals breathe as well as respire
- CO_2 is released during respiration and is released outside the animal body.
- Animals obtain their glucose by the breakdown of carbohydrate molecules.

(8) Light Reaction

- Occurs in presence of light
- Occurs in grana of chloroplast
- End product: O_2 , ATP, NADPH

Dark Reaction

- Occurs in presence or absence of light
- Occurs in stroma of chloroplast
- End product: Glucose

- (9) a → Pepsin
b → Lactic acid

- (10) (a) Acid helps in activating propepsin to pepsin. It also helps in killing of bacteria.

(b)

- (11) (a) Alveoli covered with blood capillaries helps in exchange of gases between membrane of alveoli and surrounding capillaries.

- (b) The cartilaginous rings prevents the collapse of Trachea and supports the neck

- (12) (a) During winters, the surrounding temperature is very low. So there is less sweating, leading to less water losses. So, we need to pass the excess urine during winters.

- (b) skin, lungs, liver

- (c) green glands and malpighian tubules

(13)

(i)

4 → Left atrium
5 → Right atrium

(ii)

3 & 6 → Vena Cava

This vein brings deoxygenated blood to the heart from various body organs.

(iii)

Artery ~~artery~~

(iv)

The blood passes through the heart twice through separate pathways. This is called double circulation. They are systemic and pulmonary circulation. This type of a circulation also helps regulating the temperature, thus making them warm-blooded.
